Clinical Condition Requiring Homecare:					
The patient is a 73-year-old male residing at home with his wife, Sharon Hopkins, who serves as his primary caregiver. He is alert and oriented to person, place, and time, though mild forgetfulness and cognitive decline consistent with early-stage Alzheimer's disease are evident. His wife reports progressive memory lapses accompanied by mood changes, frustration, and occasional belligerence and combativeness, particularly when he becomes aware of his deficits. During the visit, the patient displayed difficulty following directions, limiting his ability to participate meaningfully in skilled therapy interventions. The patient has a history of a recent fall, attributed to right knee weakness, which required hospitalization. He is status post right hip surgery, with the surgical site fully healed and no evidence of infection or need for wound care. Examination revealed multiple bruises and superficial scratches scattered across both upper and lower extremities, reportedly self-inflicted through frequent skin picking. No open wounds or active infection were noted. The patient is incontinent of bowel, managed with adult briefs, and voids small amounts of urine with a bedside urinal, with caregiver assistance as needed. He ambulates independently with a wide-based gait, without the use of an assistive device, and performs transfers independently. However, due to impaired judgment, poor safety awareness, and cognitive deficits, he requires continuous supervision to ensure safety. His spouse confirmed that she manages his medications, demonstrates knowledge of his regimen, and ensures adherence, with the patient cooperative in taking medications as prescribed. The patient's spouse reports that she currently feels capable of meeting his care needs and does not wish to initiate home health services at this time. She acknowledged that if his Alzheimer's disease progresses or her caregiving capacity changes, she may reconsider supportive services in the future.
